Ficha técnica

| | |
|--|---|
| Nombre de Publicación | República Dominicana: <i>Estimaciones y proyecciones de población. Proyecciones subnacionales 1990 – 2020.</i> |
| Objetivo general del producto | Dar a conocer las estimaciones y proyecciones de población por edad y sexo, y algunos indicadores de estructura de la población, de regiones y provincias, para el período 1990-2020. |
| Descripción general del producto | En la publicación se dan a conocer los resultados de las estimaciones y proyecciones de población por edad, sexo, indicadores de estructura de la población para los años 1990-2020. También se describe la metodología utilizada para el desglose de dichas proyecciones a partir de los resultados obtenidos en las estimaciones y proyecciones de población por grupos de edad y sexo del período 1950-2050, revisión 2007, presentadas en el Tomo I. |
| Año de inicio del producto estadístico | 2008 |
| Publicación de la metodología | Pertenece a la serie de publicaciones que dan cuenta de los resultados y la metodología utilizada para la elaboración de las estimaciones y proyecciones de población 1950-2050. |
| Tipo de levantamiento | Recopilación e integración de información censal y de revisión de fuentes de información relacionada con el nivel y estructura de los factores demográficos. |
| Periodicidad del levantamiento de la información | Revisión anual |
| Cobertura geográfica | Total nacional, regional y provincial |
| Fuentes de información | Registros administrativos, las encuestas demográficas y de salud, encuestas de hogares, censos de población de la República Dominicana, información sobre dominicanos en censos y registros administrativos de otros países. |
| Fecha de la publicación | Octubre de 2009 |
| Medios utilizados para la difusión de las publicaciones | Impreso, digital y publicación en línea a través de la página Web de la ONE. |
| Datos del contacto | Director Nacional de la Oficina Nacional de Estadística: Pablo Tactuk. Tel. 809-682-7777, Ext. 277 email: pablo.tactuk@one.gob.do Gerente de Estadísticas Demográficas, Sociales y Culturales: Pedro Alvarez. Presentación

Estimaciones y proyecciones subnacionales de población 1990–2020, es un trabajo sin precedentes en el que hacer demográfico de nuestro país, en otras oportunidades se había intentado hacer proyecciones subnacionales, pero es ahora cuando mediante la aplicación del Método de los Componentes se ha logrado disponer de unas proyecciones desagregadas a nivel de provincia.

Estas estimaciones y proyecciones de población arrojan resultados por regiones y provincias de la población por año calendario y grupos quinquenales de edad; del mismo modo, se presentan indicadores de la estructura de la población para las mismas áreas político-administrativas.

Se reconoce ampliamente que las proyecciones de población, por sexo y edad, tanto al nivel nacional como para las diferentes áreas geográficas y político-administrativas de un país, constituyen una herramienta de gran utilidad para la planificación económica y social. La evolución probable de la población total en el futuro próximo es un elemento fundamental para la determinación de las demandas sociales y la elaboración de planes y programas en diversos campos del desarrollo, tales como la generación de empleos productivos, la producción de bienes y servicios económicos, la construcción de establecimientos educativos y de salud, la formación de recursos humanos en estas áreas, la construcción de viviendas y soluciones habitacionales, entre otros de similar importancia.

Como es de suponer, la calidad y utilidad potencial y efectiva de las proyecciones de población dependen estrechamente del grado en que estén basadas en análisis cuidadosos de las tendencias, pasadas y recientes, de los componentes del cambio demográfico -fecundidad, mortalidad y migración-, y sus relaciones con los aspectos sociales, culturales y económicos, así como de la consideración prestada a las tendencias y relaciones al formular las hipótesis de evolución futura de los componentes indicados.

El cumplimiento de estos requisitos descansa a su vez en la disponibilidad de información confiable, detallada y oportuna sobre las variables de interés, por lo que a medida que se producen nuevas y mejores estadísticas, se plantea la necesidad de la revisión y actualización de las proyecciones.

La presente publicación contiene información útil para el cálculo de indicadores, entre ellos los que se refieren al seguimiento de las Metas de los Objetivos del Milenio, pues ofrece una estimación de la población para cada grupo etario y durante el período de referencia 1990-2015.

Adicionalmente, en el proceso de estimación, evaluación y análisis de los componentes demográficos para el período base de la proyección, se diseñaron aplicaciones especiales para planillas de cálculo electrónico Excel, las cuales permiten obtener y compatibilizar las estimaciones provenientes de los métodos indirectos de estimación demográfica, que sirvieron de insumo para la proyección de la población.

Lic. Pablo Tactuk
Director Nacional de Estadística

1. Introducción

La ONE ha hecho un gran esfuerzo para elaborar las proyecciones subnacionales y conciliarlas con la proyección nacional, acción detenida a fines de 2006, debido a las diferentes versiones por las que pasó la proyección nacional, finalizada oficialmente en enero de 2008.

Con los resultados finales de las proyecciones nacionales, fue retomado el tema de las proyecciones derivadas, incluidas las proyecciones subnacionales, tarea que se transformó en una necesidad, debido a la proximidad del censo de 2010. Todo lo que se había realizado anteriormente, desde 2006, opciones de técnicas, de métodos y cálculos, quedó plasmado en planillas, textos y una experiencia inestimable, formando una base importante para la elaboración de las presentes proyecciones subnacionales.

Para que el presente trabajo fuera útil a los fines de los Objetivos de Desarrollo del Milenio (ODM) las poblaciones proyectadas abarcan el período 1990-2015, pero, por la proximidad del 2015, se decidió prolongar la proyección hasta 2020.

Hay que resaltar que el trabajo fue hecho en dos etapas. En la primera se definieron las poblaciones provinciales del año 2000 como base o punto de partida, las cuales fueron proyectadas hasta 2020. Esto porque la mayor parte de los insumos demográficos adecuados para poder hacer una proyección por componentes provinciales se localizan alrededor del censo de 2002 y no del de 1993.

En esta primera etapa, los procedimientos adoptados fueron los tradicionales en demografía, con utilización de tasas de mortalidad, fecundidad y saldos migratorios (Método de los Componentes). En la segunda etapa se retroproyectaron las poblaciones a partir del año 2000 hacia atrás, hasta 1990, utilizando apenas las tasas de mortalidad y los saldos migratorios, sin necesidad de valerse de la fecundidad. Todos estos procedimientos son explicados con más detalle en lo que sigue de este documento.

2. Supuestos iniciales

2.1. Población base de las provincias

Las poblaciones base de las provincias fueron fijadas para el año 2000 como punto de partida y no las de 1993 por causa de la mejor calidad y cantidad de los insumos alrededor del VIII Censo de Población y Vivienda de 2002. Para definir la población base de cada provincia en el año 2000, se hizo una interpolación de la población total por sexo entre los censos de 1993 y 2002, distribuyendo estas poblaciones totales de cada provincia por grupos de edad con su correspondiente estructura provincial para el censo de 2002. Fue hecho el ajuste de la población por sexo y grupo de edad en la misma proporción que el ajuste hecho por efecto de omisión censal para el total de la población nacional, pues no se encontró ningún otro criterio más objetivo para estimar niveles diferenciales de omisión entre provincias.

La suposición básica de estos procedimientos es que en un período de dos años (entre 2000 y 2002), los cambios ocurridos en la estructura por edad de la población fueron, seguramente, pequeños y no significativos y la omisión diferencial por sexo y edad no difiere mucho entre las provincias. De todas formas, no hay disponibles otros datos necesarios para proceder de otra manera.

2.2. Mortalidad y regionalización de las provincias

Para la elaboración de las proyecciones nacionales se dispuso de las defunciones registradas en la Secretaría de Estado de Salud Pública y Asistencia Social (SESPAS) del período 1986 al 2004. Estas fueron sometidas a un proceso de verificación, este trabajo que fue realizado por un equipo interinstitucional compuesto por personal de SESPAS, del Consejo Nacional de Población y Familia (CONAPOFA), y personal técnico de la ONE, bajo la supervisión del consultor internacional Manuel Rincón, teniendo como resultado una base de datos de defunciones depurada.

De la explotación de la base de datos de defunciones se dispuso de una serie de tabulados por grupos de edad, sexo y año calendario de las defunciones por provincia y regiones. Para fines del cálculo de la mortalidad, las provincias fueron agrupadas en 6 regiones que se explicarán más adelante.

Se obtuvo también una segregación por edad en días al momento de morir de los menores de un año, para determinar el factor de separación (f_0) de las muertes infantiles. A pesar de las deficiencias del registro de los hechos vitales, estas informaciones son de vital importancia para la elaboración de las tablas de mortalidad por sexo de cada provincia y región.

Para establecer la mortalidad infantil para las 32 provincias y 6 regiones, se procedió en primer lugar a determinarla por métodos indirectos, con información sobre hijos nacidos vivos e hijos sobrevivientes, resultantes del VIII Censo de Población del año 2002, usando el programa PANDEM del Centro Latinoamericano y del Caribe de Demografía (CELADE). Los resultados obtenidos mediante este procedimiento no fueron satisfactorios pues resultaron ser muy elevados con respecto a los niveles encontrados en las encuestas ENDESA realizadas en el país en años recientes.

Debido a estos resultados, fueron utilizados los datos de mortalidad infantil de la ENDESA 2002, la cual trae valores a nivel de provincia. En algunas de ellas no hay datos debido al pequeño tamaño de la muestra, por lo que fueron utilizados procedimientos específicos para poder estimar valores aproximados.

Para determinar el subregistro de las defunciones, las muertes registradas fueron sometidas a un proceso de evaluación por medio de técnicas indirectas. Al igual que en la proyección nacional, se centraron las defunciones del 2000 al 2004 promediándolas al año 2002 y, con información de la población del censo de 2002, se aplicó el método de Brass de la estructura de las defunciones y el método de Preston.

Mediante este procedimiento se obtuvo una serie de informaciones para provincias y regiones de los niveles de omisión del registro de las defunciones de los mayores de 5 años, para cada sexo. Con esta información se pudo llegar al cálculo de las tablas de vida por provincias y regiones.

El factor de separación de las muertes infantiles también se utiliza en la elaboración de las tablas de vida y se calcula con la información sobre las muertes de menores de un año obtenida de estadísticas vitales, para lo cual, como se mencionó anteriormente, se tomó la información de las defunciones de los menores de un año, de la base de datos de defunciones suministrada por SESPAS, desglosada por los períodos sub-anales (menores de 1 día, 1 a 6 días, 7 a 29 días, 1 a 5 meses, 6 a 11 meses), estandarizados para este cálculo. Su importancia estriba en que este factor está estrechamente relacionado con los niveles de mortalidad infantil.

Con la población censada por provincia en el 2002, las tasas de mortalidad corregidas por la metodología indicada y los factores de separación, se produjo un juego de tablas de vida por sexo, en las cuales también se determinó la esperanza de vida al nacer (e_0), para cada una de las provincias y para las regiones operativas.

Para los fines de esta proyección subnacional se crearon seis regiones operativas. Las provincias fueron agrupadas para superar el problema de las oscilaciones de los datos de mortalidad por

edad existentes entre provincias. Estas seis regiones presentaban características demográficas y socio-económicas homogéneas, con los siguientes indicadores¹: esperanzas de vida al nacer por sexo (DP); diferencia por sexo de la esperanza de vida al nacer (DP); mortalidad Infantil (IP); diferencia por sexo de la mortalidad infantil (DP); omisión relativa de las defunciones por sexo (IP); factor de separación por sexo (IP); tasa global de fecundidad (TGF) (IP); edad media de la población (DP); tasa de analfabetismo de la población (IP); porcentaje de hogares con jefatura femenina (IP); porcentaje de hogares con conexión de agua dentro de la vivienda (DP); porcentaje de hogares con conexión de agua dentro de la vivienda o fuera de la vivienda (DP); porcentaje de hogares sin servicio sanitario (IP); porcentaje de hogares sin hacinamiento (DP); porcentaje de menores de 5 años (IP) y promedio de habitantes por vivienda (IP). Las 6 regiones con sus respectivas provincias quedaron como sigue:

Región 1: Distrito Nacional y Santo Domingo;

Región 2: Puerto Plata, Valverde, Santiago, Hermanas Mirabal, La Vega y San Pedro de Macorís;

Región 3: San Cristóbal, La Romana, Monte Cristi, Duarte, María Trinidad Sánchez, Sánchez Ramírez y Peravia;

Región 4: Samaná, La Altagracia, Barahona, Espaillat, Monseñor Nouel, Santiago Rodríguez y Azua;

Región 5: Independencia, Hato Mayor, San José de Ocoa, Pedernales y San Juan

Región 6: Monte Plata, El Seibo, Dajabón, Baoruco y Elías Piña.

2.3. Fecundidad

La fecundidad fue medida con la tasa global de fecundidad (TGF) usando dos fuentes de información diferentes y técnicas indirectas debido a la mala calidad del registro de nacimientos. En el primer caso fue utilizado el método P/F con la información del Censo de Población y Vivienda del 2002. Esta información fue contrastada con las TGF obtenidas de la encuesta ENDESA 2002. Los valores encontrados por provincia a partir de estas dos fuentes son muy similares por lo que se decidió hacer una media de los mismos para llegar al valor adoptado para cada provincia. Las tasas específicas de fecundidad fueron obtenidas a través del referido censo de 2002.

2.4. Migración

La migración por provincia está integrada por dos componentes, la migración interna y la migración internacional, teniendo cada una de ellas sus propias particularidades y por lo tanto requieren un análisis por separado. El saldo migratorio total para cada provincia es el resultado de la suma del saldo migratorio interno (interprovincial) y del saldo migratorio

1- Si la variable es directamente proporcional al grado de desarrollo demográfico y/o socio-económico-cultural, se indica entre paréntesis como DP, si es indirectamente proporcional, se indica como IP.

internacional. El saldo de la migración total del país debe ser igual al saldo neto migratorio internacional, debido a que la suma de todos los saldos internos de las provincias debe ser igual a cero, ya que los que emigran de una determinada provincia son absorbidos como inmigrantes en otras.

2.4.1 Migración internacional

Para la migración internacional se ha asumido que, en ausencia de información precisa a nivel de provincia de los patrones migratorios hacia el exterior del país, los saldos migratorios internacionales del total país de la proyección nacional afectan por igual a todas las provincias, por lo que estos saldos migratorios internacionales fueron distribuidos proporcionalmente por edad y sexo a la población por edad y sexo de cada provincia.

2.4.2 Migración interna

Procesando la base de datos del censo de 2002 se obtuvo la cantidad de migrantes interprovinciales (emigrantes e inmigrantes) mayores de 5 años, y por ende los saldos de la migración interna de los últimos 5 años previos al censo (1997-2002), segregados por provincia, por sexo y grupos quinquenales de edad.

Los saldos migratorios de los nacidos en el período de referencia (1997-2002), o sea, menores de 5 años, fueron calculados por métodos aproximados con base a las razones niño-mujer por provincia, derivadas del censo del 2002. Estas migraciones netas fueron calculadas con la ecuación:

$$M_{0-4} = \frac{1}{4} * (CWR_0 * \text{Mujeres}_{\text{migrantes (15-44)}})$$

Donde

M_{0-4} : son los migrantes para las edades de 0 a 4 años, y

CWR_0 : son las razones de hijos en edades 0 a 4 años con las mujeres con edades de 15-44 años.

y se calcula:

$$CWR_0 = \text{Población}_{(0-4)} / \text{Mujeres}_{(15-44)}$$

A estos saldos netos migratorios basados en la información censal, se les hicieron los ajustes por omisión en los mismos niveles por sexo y edad que a la población total del país.

3. Proyección de los componentes por provincia y región

3.1. Mortalidad infantil y esperanza de vida al nacer

El punto de partida es la secuencia de datos de mortalidad infantil por sexo de la proyección nacional y los datos de las regiones, estimados para 2002.

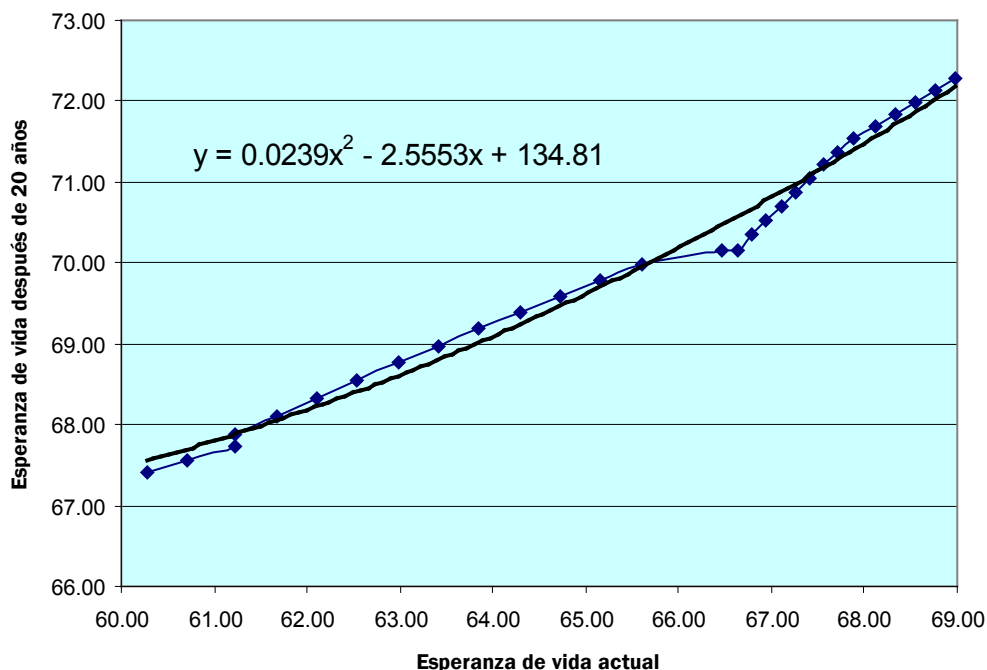

Para la proyección de la esperanza de vida al nacer se procedió a determinar los pivotes a ser utilizados en la curva logística, como pivote inicial la esperanza de vida al nacer estimada en 2002 para cada región y como segundo pivote la esperanza de vida al nacer que se espera tenga cada región dentro de 20 años. Para determinar este segundo pivote se hizo una relación de las esperanzas de vida estimadas y proyectadas para el país entre 1950 y 2050 con su correspondiente 20 años después. De esta relación se obtuvo para cada sexo las curvas siguientes:

Hombres: $e_{0(20)} = 0.0239(e_{0i})^2 - 2.5553(e_{0i}) + 134.81$

Mujeres: $e_{0(20)} = 0.027(e_{0i})^2 - 3.4192(e_{0i}) + 182.81$

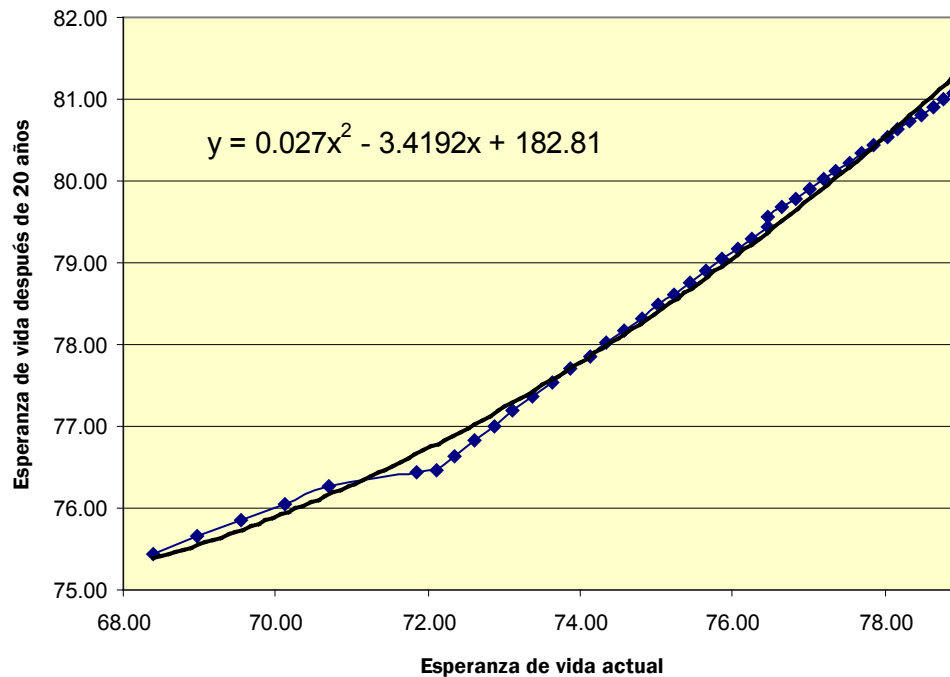

Comportamiento de la esperanza de vida al nacer de los hombres después de haber transcurrido 20 años.

Comportamiento e0 hombres

Comportamiento de la esperanza de vida al nacer de las mujeres después de haber transcurrido 20 años.

Comportamiento e0 Mujeres

La curva logística utilizada en la proyección de la esperanza de vida al nacer es de la forma:

$$q_0(t) = k_1 + \frac{k_2}{1 + e^{(a-bt)}}$$

En la que:

k_1 = Límite inferior de la esperanza de vida al nacer: 40 años (para ambos sexos).

k_2 = Límite superior de la esperanza de vida al nacer: 88 años para las mujeres y 81 para los hombres.

Los resultados de la esperanza de vida al nacer para cada uno de los períodos y sexo de las diferentes regiones son los que se muestran en el cuadro siguiente:

Esperanzas de vida al nacer estimadas y proyectadas por período, según sexo y región.

| Región | Período | | | | | |
|----------------|-----------|-----------|-----------|-----------|-----------|-----------|
| | 1990-1995 | 1995-2000 | 2000-2005 | 2005-2010 | 2010-2015 | 2015-2020 |
| Hombres | | | | | | |
| Región 1 | 64.46 | 65.60 | 66.71 | 67.78 | 68.80 | 69.78 |
| Región 2 | 68.11 | 69.03 | 69.90 | 70.73 | 71.52 | 72.27 |
| Región 3 | 66.37 | 67.38 | 68.35 | 69.28 | 70.17 | 71.01 |
| Región 4 | 65.80 | 66.84 | 67.85 | 68.82 | 69.74 | 70.63 |
| Región 5 | 62.76 | 64.04 | 65.29 | 66.50 | 67.67 | 68.79 |
| Región 6 | 67.28 | 68.23 | 69.15 | 70.03 | 70.86 | 71.65 |
| Mujeres | | | | | | |
| Región 1 | 72.22 | 73.25 | 74.24 | 75.19 | 76.10 | 76.96 |
| Región 2 | 74.25 | 75.11 | 75.93 | 76.72 | 77.47 | 78.18 |
| Región 3 | 72.85 | 73.83 | 74.76 | 75.66 | 76.51 | 77.32 |
| Región 4 | 72.56 | 73.56 | 74.52 | 75.44 | 76.32 | 77.16 |
| Región 5 | 67.52 | 69.07 | 70.58 | 72.03 | 73.42 | 74.74 |
| Región 6 | 68.62 | 70.04 | 71.41 | 72.73 | 74.00 | 75.20 |

Con el juego de tablas de vida realizadas para cada región para el año 2002 y conciliadas éstas con la tabla de vida nacional para ese mismo año, se procedió a la elaboración de las tablas de vida por sexo y período para cada región. Esta labor se hizo mediante la utilización del **PAS** del Buró del Censo de los Estados Unidos, que es un sistema de hojas de cálculo para el análisis demográfico de población. Con la planilla **INTLTF** se interpolan las tablas femeninas y con la **INTLTM** las masculinas, entre una tabla inicial (que son las obtenidas para 2002) y una tabla de vida límite, en este caso, las usadas en las proyecciones nacionales con esperanzas de vida de 81 y 88 años para hombres y mujeres, respectivamente.

Con la interpolación de las tablas de vida se obtienen para cada período y sexo las tasas de mortalidad infantil asociadas a las esperanzas de vida al nacer proyectadas.

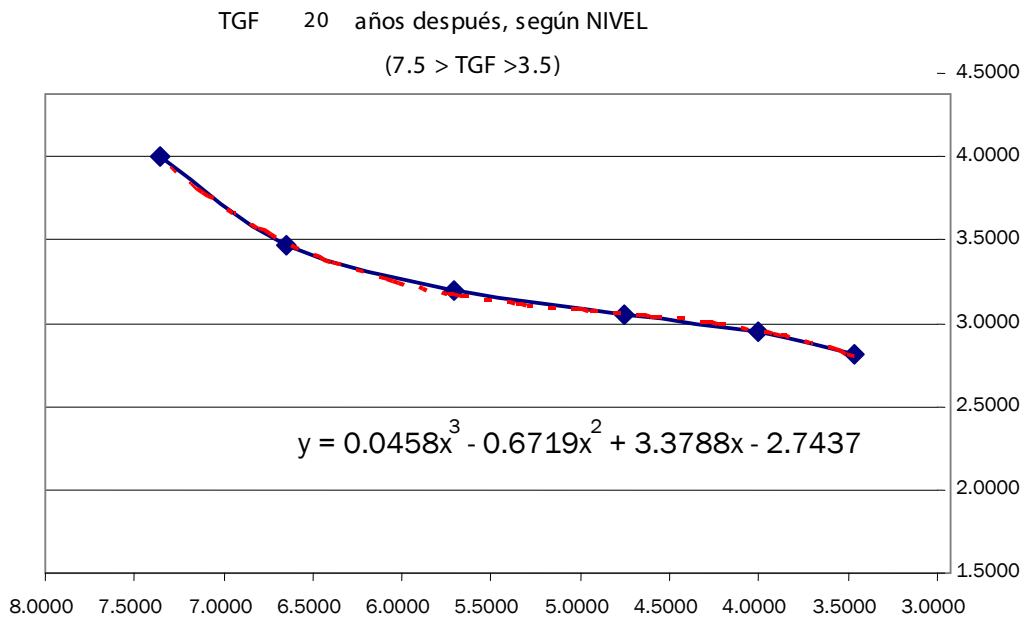

3.2. Nivel y estructura de la fecundidad

Como se expuso anteriormente, la fecundidad fue medida con la tasa global de fecundidad (TGF) y sus valores iniciales corresponden al 2002 y las estructuras son las del censo de 2002.

Para la proyección de la **TGF** se procedió de manera similar a como se hizo en el caso de la esperanza de vida al nacer, ya explicada anteriormente. Con la fecundidad, los datos permitieron una proyección por provincia, sin necesidad de agruparlos por las 6 regiones como en el caso de la mortalidad.

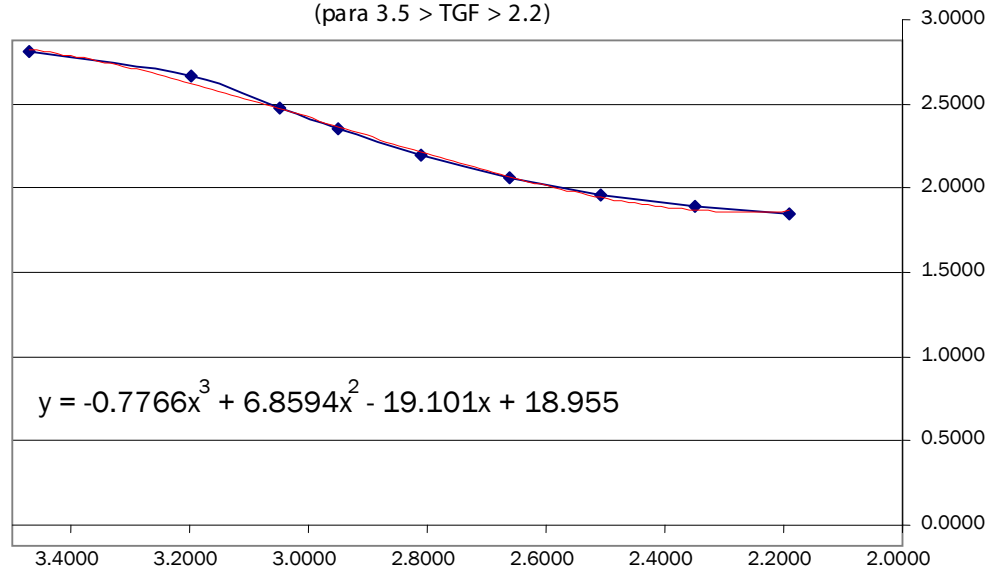

Sin embargo, con las **TGF**, al observar el comportamiento que tiene esta variable en la proyección del país, se ha optado como mejor solución, para evitar rupturas en la función, hacer dos series de asociaciones. Una en la cual las tasas van de 7.5 a 3.5 (en este rango se observan pendientes más fuertes en el descenso de la fecundidad del país) y otra en la que las tasas van de 3.5 a 2.2 (para este rango el descenso es más lento). Los resultados están en los gráficos siguientes, con las respectivas funciones.

Comportamiento de la TGF del país (entre 7.5 y 3.5) después de haber transcurrido 20 años.

Comportamiento de la TGF del país (entre 3.5 y 2.2)
después de haber transcurrido 20 años

TGF 20 años después, según NIVEL
(para $3.5 > \text{TGF} > 2.2$)

Con la información del censo del año 2002 sobre el total de hijos e hijas del último año se obtuvieron tasas de fecundidad para cada una de las provincias. Estos resultados, independientemente de los problemas inherentes a la recolección censal, resultan de interés, en este caso que nos ocupa, los niveles de la TGF obtenidos son muy similares a los que presenta la encuesta ENDESA 2002, para las diferentes provincias.

Para las proyecciones subnacionales se están asumiendo los promedios de los dos estudios, para de alguna manera suavizar las pequeñas diferencias entre ambos estudios.

La TGF fue proyectada usando una curva logística de la forma:

$$\text{TGF}_i = k_1 + \frac{k_2}{1 + e^{(a+bt)}}$$

Como límite inferior se usó una tasa igual a 2.1.

En la proyección de la estructura de la fecundidad debe considerarse que ésta no es independiente del nivel. La distribución relativa de la tasa de fecundidad por edades depende en definitiva del nivel de la fecundidad correspondiente. En la medida en que la fecundidad

desciende, apartándose de los niveles naturales, la estructura o forma de la curva tendrá que ver con la intensidad del descenso en los diferentes grupos de edades, el cual, por cierto puede darse de múltiples formas, según cómo actúen las llamadas variables intermedias.

Para estudiar la tendencia observada en el pasado, como para hacer la proyección de la fecundidad (dado que la estructura se relaciona con el nivel de la fecundidad) se hace a través de la función de Gompertz, que se aplica en la proyección de la misma.

Para el estudio de la tendencia es necesario disponer al menos de dos estructuras observadas en un pasado reciente. Si estas estructuras se asimilan a una curva de Gompertz es posible aplicar el procedimiento para proyectar la fecundidad. La curva de Gompertz es de la siguiente forma:

$$\frac{F(x)}{TGF} = A B^x$$

Por lo tanto, en el caso de proyección de la estructura de la fecundidad por provincia utilizando la función de Gompertz, fueron usadas las estructuras de las tasas específicas de fecundidad resultantes del censo del 2002 para cada provincia como tasas observadas, y como estructura estándar se asumió la utilizada en las proyecciones nacionales.

**Tasas específicas de fecundidad y TGF, según
provincia para el periodo 2000-2005**

| Provincia | Grupo de edad | | | | | | | TGF |
|------------------------|---------------|--------|--------|--------|--------|--------|--------|------|
| | 15-19 | 20-24 | 25-29 | 30-34 | 35-39 | 40-44 | 45-49 | |
| Distrito Nacional | 0.0504 | 0.1467 | 0.1354 | 0.0936 | 0.0372 | 0.0089 | 0.0019 | 2.37 |
| Santo Domingo | 0.0884 | 0.1726 | 0.1431 | 0.0989 | 0.0416 | 0.0108 | 0.0026 | 2.79 |
| Peravia | 0.1286 | 0.1879 | 0.1364 | 0.0875 | 0.0350 | 0.0088 | 0.0020 | 2.93 |
| San Cristóbal | 0.1265 | 0.1940 | 0.1456 | 0.0960 | 0.0394 | 0.0101 | 0.0024 | 3.07 |

3.3. Migración

3.3.1 Migración internacional por provincia

Como se explicó anteriormente en el ítem 2.4.1 los saldos internacionales se obtuvieron con la distribución por sexo y edad del saldo migratorio internacional total usado en las proyecciones nacionales, y proporcionalmente a la población de cada provincia. Los saldos migratorios internacionales del total del país se fueron distribuyendo proporcionalmente a la población provincial resultante de la proyección de cada período. El mismo procedimiento fue utilizado para la retro-proyección (1990-2000).

3.3.2 Migración interna por provincia

El cálculo de los saldos migratorios internos por provincia del período 1997-2002 está explicado en el ítem 2.4.2. A partir del año 2000, tanto la proyección como la retroproyección fueron hechas manteniéndose la misma estructura por sexo y edad de este período. Se hizo la hipótesis de una disminución paulatina de los saldos migratorios, de tal manera que en 2050 los mismos serán, en términos absolutos, aproximadamente el 50% de los del período 1997-2002. La manera de respetar este horizonte fue reducir paulatinamente los saldos, en cada quinquenio, en un 5% con respecto al período anterior, comenzando por 2000-2005. Con respecto al período 1990-2000 se mantuvieron los mismos saldos del período 1997-2002, arrojadas por el censo del 2002.

4. Proyección

4.1. Organización de los insumos para la proyección por provincia

Todas las informaciones obtenidas en las etapas anteriores fueron sistematizadas en una planilla de insumos, de tal forma tener juntos y organizados los datos necesarios para hacer la proyección con el Método de los Componentes. Estas informaciones, siempre a nivel de cada provincia, excepto las tablas de vida a nivel regional, son las siguientes:

- La población base en el año 2000 por sexo y edades ajustada, punto de partida de la proyección;
- Las relaciones de supervivencia por sexo y edad de los períodos 2000-2005, 2005-2010, 2010-2015, 2015-2020 y los de la retro-proyección, o sea, 1990-1995 y 1995-2000;
- Los saldos migratorios internacionales de los períodos 2000-2005, 2005-2010, 2010-2015, 2015-2020 y los de la retro-proyección, o sea, 1990-1995 y 1995-2000;
- Los saldos migratorios internos de los períodos 2000-2005, 2005-2010, 2010-2015, 2015-2020, y los de la retro-proyección, o sea, 1990-1995 y 1995-2000 y, finalmente,
- Las tasas globales de fecundidad de los períodos 2000-2005, 2005-2010, 2010-2015 y 2015-2020 y sus respectivas tasas específicas por edad de la madre (en el caso de la fecundidad, no fue necesaria información entre 1990 y 2000)

4.2. Proyección de las poblaciones de las provincias

Organizada toda la información necesaria se procedió a la realización de las proyecciones provinciales. Fue aplicada a cada una de ellas el Método de los Componentes, o sea, fue hecha una proyección específica para cada provincia a partir de 2000. Se debe notar que la mortalidad de las provincias fue obtenida a partir de las regiones dentro de las cuales estaban incluidas cada una de ellas.

Las otras variables fueron específicas de cada provincia. Se debe notar además que en el caso de los dos quinquenios de la retro-proyección, (1990-1995 y 1995-2000) se aplicó el Método de los Componentes hacia atrás, partiendo de la población base de cada provincia, o sea, a partir de 2000.

4.3. Conciliación entre la proyección de las provincias y la nacional

Hecha la proyección de la población de cada provincia por el Método de los Componentes y habiendo tenido en cuenta tomar las previsiones de lugar para que haya coherencia entre las variables provinciales y las nacionales, la suma de todas las poblaciones provinciales regularmente arroja pequeñas diferencias con respecto a la población de la proyección nacional, puesto que estas son calculadas de forma independiente.

Por este motivo, la proyección fue hecha en etapas, correspondientes a los cuatro quinquenios de la proyección (2000-2005, 2005-2010, 2010-2015 y 2015-2020) y a los dos de la retro-proyección, o sea, al final de cada una de estas etapas fue hecho un pequeño ajuste de conciliación con el total nacional. Por ejemplo, en la primera etapa, al final de la proyección del quinquenio 2000-2005 fue hecho un ajuste para que la suma de las proyecciones de las provincias para cada grupo de edad y sexo sea igual a la del país como un todo, y así sucesivamente.

4.4. Población por grupos de edad por año calendario

Uno de los objetivos de la proyección por provincia es que estas informaciones sirvan como denominador para el cálculo de los indicadores de los Objetivos de Desarrollo del Milenio.

Luego de obtenidas todas las poblaciones que cubren el período de la proyección (1990-2020), se calcularon las poblaciones por años calendario por grupo de edad y sexo, mediante la utilización de los Multiplicadores de Karup-King a las poblaciones por grupos de edad de los años terminados en 0 y 5, de la siguiente forma:

Sean N_x^i las poblaciones de edad x en los años **0, 5, 10 y 15**; N_x^j la población del año calendario **j (entre i y i+5)**; y, mk_{ij} Multiplicadores de Karup-King. Entonces se tiene:

$$N_x^j = \sum_{i=1}^4 (mk_{ij} * N_x^i) \quad \text{con } j=1,2,3,4$$

Multiplicadores de Karup King Años calendario

| Intervalo inicial | | | | | | |
|-------------------|--------|---------|---------|---------|---------|--------|
| | 0 | 1 | 2 | 3 | 4 | |
| 1 | 1.0000 | 0.6560 | 0.4080 | 0.2320 | 0.1040 | 0.0000 |
| 2 | 0.0000 | 0.5520 | 0.8560 | 0.9840 | 1.0080 | 1.0000 |
| 3 | 0.0000 | -0.2720 | -0.3360 | -0.2640 | -0.1280 | 0.0000 |
| 4 | 0.0000 | 0.0640 | 0.0720 | 0.0480 | 0.0160 | 0.0000 |
| Intervalo central | | | | | | |
| | 5 | 6 | 7 | 8 | 9 | |
| 1 | 0.0000 | -0.0640 | -0.0720 | -0.0480 | -0.0160 | 0.0000 |
| 2 | 1.0000 | 0.9120 | 0.6960 | 0.4240 | 0.1680 | 0.0000 |
| 3 | 0.0000 | 0.1680 | 0.4240 | 0.6960 | 0.9120 | 1.0000 |
| 4 | 0.0000 | -0.0160 | -0.0480 | -0.0720 | -0.0640 | 0.0000 |
| Extremo final | | | | | | |
| | 10 | 11 | 12 | 13 | 14 | |
| 1 | 0.0000 | 0.0160 | 0.0480 | 0.0720 | 0.0640 | 0.0000 |
| 2 | 0.0000 | -0.1280 | -0.2640 | -0.3360 | -0.2720 | 0.0000 |
| 3 | 1.0000 | 1.0080 | 0.9840 | 0.8560 | 0.5520 | 0.0000 |
| 4 | 0.0000 | 0.1040 | 0.2320 | 0.4080 | 0.6560 | 1.0000 |

De esta forma se consiguen las poblaciones para cada provincia por sexo y grupo de edad para cada año calendario a partir de 1990 y hasta el año 2020.

4.5. Resultados de las estimaciones y proyecciones provinciales de población 1990-2020

Cuadro 1
República Dominicana
Estimaciones y proyecciones de la población total por sexo
y relación de masculinidad, según año calendario.
Período 1990-2015

| Año | Población | | | Índice de Masculinidad |
|------|------------|-----------|-----------|------------------------|
| | Total | Hombres | Mujeres | |
| 1990 | 7,179,330 | 3,612,513 | 3,566,817 | 101.3 |
